Abstract

This study aims to determine the impact of investments in the agricultural sector to the Gross Domestic Regional Products (GDRP) of agriculture in West Java. The sample was taken from 26 regions in West Java. The results showed that Foreign Capital Investment (FCI) and Exchange rate have positive and significant impact to GDRP. Domestic Capital Investment (DCI) has positive effect of labor but not significantly to GDRP. BI Rate has significant negative effect on GDRP. Fixed effect model allows the analysis of individual securities to be interpreted as the position of the relative potency of a districts / cities. There are nine districts/cities that have a significant positive intercept. These districts are categorized as areas which contribute highly to agricultural sector. The highest sector is in Indramayu district, the second is in Sukabumi, Banjar, Subang and so on. Cimahi has the lowest score of intercept. Negative intercept is an area of low agricultural contribution, generally those which are categorized as industrial areas, such as Bandung, Cirebon, Bogor, Bekasi, Karawang. These areas are classified as industrial area which have negative contribution of agricultural sector to the GDRP.

Keywords: GDRP, Foreign Capital Investment, Domestic Capital Investment, Exchange Rate, BI rate.

INTRODUCTION

Indonesia is one of the agricultural countries which have greater potential in the agricultural sector. In the Medium Term Development Plan of the Ministry of Agriculture phase-3 (2015 - 2019), the agricultural sector is still an important sector in national economic development. The strategic role of agriculture depicted in its contribution in providing food and industrial raw materials, contributor to Gross Domestic Products (GDP), Foreign exchange earnings, the main employer, the main source of income for rural households, providers of feed ingredients and bioenergy, play an important role in efforts to reduce greenhouse gas emissions. Realization of national investment per sector in 2007-2011 is described as contained in Table 1.

Agricultural investment sent by the major capital owners are considered less beneficial for domestic and foreign investors. This happens because agricultural sector has a high risk of uncertainty which includes water availability, climate variability and the nature of policy. These responds to mitigate greenhouse emission and adapt to change that will intensify the traditional risks by farmers in managing and fluctuations in commodity

markets (Mallawaarachchi, et.al.). The agricultural sector in West Java has contributed to increase foreign exchange earnings and is expected to encourage investors to invest in it. Contribution on national investment needed in 2007-2012 is described as contained in Table 2.

Based on Central Statistics Agency (BPS) in 2006, the agricultural sector is a sector which absorbs highest labor for equally to 44.6%. Their contribution to Gross Domestic Products (GDP) is only 13.3%. The unbalance of GDP contribution and the amount of labor absorbed means that the level of labor productivity in the agricultural sector is the lowest. The industrial sector contributes 28.9% of national GDP with 12.1% labor absorption. As a result, the welfare of households working in agriculture is lower than those who are employed in industry (www.bappenas.go.id).

The agricultural sector is considered as a static sector and has a negative role in the economic growth for a country that plays an active role. Since 1980s, there was a significant change in thinking in public policy that sees the agricultural sector more positively. The sector is believed to play a role as a leader in the sector of economic development (Tambunan, 2010; Setiono 2010; Syafrizal, 2012; Refi, 2014).

Gross Domestic Regional Product (GDRP) or better known as Regional Income is the statistics that summarize the acquisition of the value added of all economic activity in a region (PPSK, 2008). Gross Domestic Regional Product (GDRP) is calculated in two ways: (1) On the basis of current prices, (2) On the basis of constant prices. Gross Regional Domestic Product (GRDP) can be translated into three terms (www.bps.go.id), namely: (1) Production Approach, (2) Income Approach, (3) Expenditure approach. Agricultural sector contribution to GDRP in West Java showed a declining trend since 1975 by 34.6%, in 1990 21.6% and in 2004 to 12.3%. It was then switched to the industrial sector which contributes to the GDP amounted to 53.8% (Hill, 2008). Of contributions to GDRP of agriculture sector in West Java in 2014 to 8.73% was below the processing industries amounted to 43.61% and trade, hotels and restaurants 15.25% (West Java in figures, 2015).

Investment (Subandi, 2012) is the expenditure made by investors concerning the use of resources such as equipment, buildings, production equipment, and other new machines or supplies that are expected to benefit from the investment. Foreign Capital Investment (FDI) is an investment made by a company in one country to a company in another country. It is then intertwined relationships between companies holding with its affiliated companies which are collectively referred to as Transnational Corporation (TNC).

Domestic Investment (DCI) is the investment activity which conducts business in the territory of the Republic of Indonesia (NKRI) carried out by a domestic investor using domestic capital. Investment provisions are stated and regulated in the Law No. 25 Year 2005 regarding Investment. Domestic Capital Investment can be carried out by individuals Indonesian Citizen (WNI), entity, or government investments in the territory of the Republic of Indonesia (NKRI).

The definition of labor forces people to work. It also consists of those people who are either ready to work or working. Exchange rate is the price of one country's currency to another country's currency rates (Mishkin, 2008). BI Rate, or interest rate set by Indonesian Bank, maintains the stability of monetary rate. The policy of BI interest rate reflects the attitude or stance of monetary policy set by Bank Indonesia (BI) which is also announced to the public. Operationally, the monetary policy stance is reflected by the policy-setting interest rate (BI Rate) which is expected to be able to give influence on money market interest rates and deposit rates and bank lending rates.

The theory of economic growth is defined as an explanation of the factors in determining the expenditure increase (output) per capita in the long term, and an explanation of how these factors interact with each other, resulting in the growth process. Here are some opinions from the theory of economic growth (Skousen, 2001; Todaro, 2006; Daryanto & Hafizrianda 2010; Kuncoro,

2013): (1) the first is theory of Solow-Swan. Economic growth depends on the increase in supply factors such as labor, capital accumulation and technology. The ratio of capital expenditure (output) can change if labor is used larger, the amount of capital will be lesser. However, if the amount of capital used is greater, the amount of labor is needed less. (2) the second is theory of Harrod-Domar; an extension of the Keynesian analysis of national economic activity and labor problem. Keynesian analysis is considered incomplete because it does not address the economic problems in long term. Harrod-Domar analyzes regarding the necessary conditions therefore the economy can grow and continue to thrive in the long term very well (steady growth).

Currently, there is no single theory which could explain the economic development of the region in a comprehensive manner, however several theories (individual) can partially help the importance of regional economic development and the factors that give influence to it. Jamzani Sodik and Didi Nuryadin (2005) conducted a study on the investment and economic growth (a case study in 26 provinces in Indonesia, pre- and post-autonomy), using the method of General Least Square (GLS). Dependent variables Gross Domestic Regional Product (GDRP) and the independent variables of Foreign Capital Investment (FCI), Domestic Capital Investment (DCI), labor force, inflation, exports, imports are described in the model specification as followed:

$$GDRP_{it} = \alpha_0 + \beta_1 FCI_{it} + \beta_2 DCI_{it} + \beta_3 LF_{it} + \beta_4 INF_{it} + \beta_5 (X-M)_{it} + \epsilon_{it}$$

variable description:

GDRP	=	The growth rate of GDRP per capita
FCI	=	The growth rate of Foreign Capital Investment
DCI	=	The growth rate of Domestic Capital Investment
LF	=	The growth rate of Labour Force of Province
INF	=	The inflation rate of the province
(X-M)	=	The level of economic openness (exports and imports) of the province
t	=	time
i	=	province
ϵ	=	Error term

This study is using panel data regression of 26 provinces during 1998-2003. It also uses the indication of domestic and foreign influence on regional economic growth. The net export effect is relatively small, while the inflation rate has no effect on regional economic growth on the observation period 2000-2003 (after the regional autonomy), where as prior to negative effect.

The study of Anita Faiziah and Sofyan (2014) about the influence of the amount of labor, exports, investment

and bank credit to the agricultural sector GDRP Aceh province is described with the model specification as follows:

$$GDRP_p = \alpha + \beta_1 Am + \beta_2 Xa + \beta_3 Ai + \beta_4 Ca + \epsilon$$

Description of variables:

GDRPp = Gross Domestic Regional Product agricultural sector Aceh

Am = The number of agricultural manpower Aceh

Xa = The export value of agricultural sector

Ai = Agricultural investment

Ca = Total bank credit agricultural sector

α = constants

$\beta_{1,2,3,4}$ = regression coefficient

ϵ = error

The study of multiple linear regression of time series data in 1999-2012 gave the result that labor had significant negative effect on exports and significant effect and investment. Meanwhile, bank credit gave positive and significant impact to GDRP.

This study describes the relationship of how GDRP influenced by investment, foreign and domestic, labor, exchange rate and interest rate in West Java (Figure 1). Hypothesis described as follows:

1. Foreign Capital Investment (FCI), Domestic Capital Investment (DCI), Labor, and rupiah exchange rate have positive influence on Gross Regional Domestic Product (GDRP) in West Java.
2. BI Rate has negative effect on the Gross Domestic Regional Product (GDRP) in West Java.

METHOD

Method used in this study is descriptive and quantitative analysis. It aims to find out the investments allocated and the influence of the agricultural sector to GRDP investment in West Java in 2007-2012. Secondary data sources in 2007-2012 were taken based on the types of panel data. Data was obtained from Promotion Coordination Board (BKPM) West Java Province, the National Socio-economic Survey (Susenas), the Central Statistics Agency (BPS), the Asian Development Bank (ADB), and Bank Indonesia (BI), with linear regression multiple use Ordinary Least Square (OLS) software Stata version 12 (Apriliawan, 2013).

Based on studies conducted Jamzani Nuryadin Sodik & Didi (2005), and Anita Faiziah & Sofyan (2014), the authors apply the model to make modifications to the model. This study uses panel data from the years 2007-2012 with the research model as followed:

$$\ln GDRP_{it} = \beta_0 + \beta_1 \ln FCI_{it} + \beta_2 \ln DCI_{it} + \beta_3 \ln L_{it} + \beta_4 \ln ER_{it} + \beta_5 BIR_{it} + \epsilon_{it}$$

Method test of panel data estimation is using Chow

Description of variables:

GDRP = Gross Domestic Regional Product agricultural sector

FCI = Foreign Capital Investment agricultural sector

DCI = Domestic Capital Investment agricultural sector

MP = Manpower agriculture

ER = rupiah exchange rate

BIR = BI Rate

i = Regions studied

t = Years studied

β_0 = Intercept

$\beta_{1,2,3,4}$ = Parameter Variable

ϵ = Error Term

Test, Lagrangian Multiplier (LM) Test, Hausman Test and classical assumption test using Multicollinearity, Heteroskedasticity test, autocorrelation test. Statistics test includes t-statistical test, z-statistic test, the coefficient of determination (R^2), and Sensitivity test (Enders, 2010).

RESULT

Chow Test (Table 3) aimed to see the results of F probability of Fixed Effect (FE). It is the probability value where Alpha is less than 0.05 or 5% on significant level and H_0 is rejected. The results of F probability of Fixed Effect (FE) on Chow Test is at 0.0000, hence Chow test states that the best model is the model Fixed Effect (FE).

Lagrangian Multiplier (LM) (Table 4) Test is done by looking at the probability of Alpha chi2 with a significance level of 5%, while H_0 is rejected. The results showed that the probability chi2 Lagrangian Multiplier (LM) Test is at 0.0005, while Hausman Test states that the best model is Fixed Effect (FE).

Hausman Test (Table 5) is performed by seeing the results of the probability of Alpha chi2 with a significance level of 5%, while H_0 is rejected. The results showed that the probability of Hausman Test is at 0.0105, while the test itself showed the best model is the model of Fixed Effect (FE).

Multi-collinearity test (Coefficient of Correlation Between Independent Variables) is performed with a partial correlation matrix (people) among regressors (Correlation Coefficient Matrix). In Table 6, it can be seen the relationship between independent variables. Based on the rule of thumb (0.80), there is no multicollinearity in the model because all the independent variables were below 0.80.

In Table 7, it shows that in hetero-scedasticities, the test conducted by Wald by looking at the results of the probability is bigger than chi2 with Alpha significance level of 5%, while H_0 is rejected. The results probability is also bigger than chi2 of the Wald test which the result

was 0,000, hence the test of hetero-scedasticity states that it has problems heteroscedasticities.

In Table 8, it shows that the auto-correlation conducted by Wooldridge Test by looking at the results of Probis bigger than Alpha F with a significance level of 5%, while H_0 is rejected. The results Probis bigger than F from Wooldridge test which the result is at 0.0000, hence the auto-correlation test states that it has a problem of autocorrelation.

BLUE assumption collision that occurred on Fixed Effect method is done in a way to treatment Fixed Effect using GLS (Generalized Least Square). According to Gujarati (2009), it is stated that GLS is an estimate of the BLUE for the model estimation method with GLS which has fulfilled the conditions ideal. As for the method of Random Effect, it does not do treatment because of the GLS method assumes that the individual errors are not correlated, as well as a combination therefore the estimation error will be more efficient and better generated model (Baltagi, 2005). The results of treatment using the GLS is described as contained in Table 9. It can be seen that the results of the regression using GLS prove that the factors which violates the assumption BLUE (Best Linear Unbiased Estimate) has been eliminated. By using GLS in this study, the absence of hetero-scedasticity or homo-scedasticity, and the absence of autocorrelation (no autocorrelation) are perfectly shown up.

T-statistic (Table 10) is used to determine whether there is influence of the independent variables individually (partial) fixed to variable. This test is performed by comparing the value of the t-stat with tables using a t-test one direction. The results of the t-statistic for the model showed (Table 11) that (1) there is positive and significant effect on Foreign Capital Investment in agricultural sector, (2) Domestic Capital Investment in agricultural sector does not significantly give effect on agricultural laborers. It also had no significant effect, (3) there is positive and significant impact on foreign exchange (4) BI Rate gives significant negative effect on GDRP of agriculture in West Java. Test of F-statistic (Table 11) is also used to determine whether there is influence of the independent variables as a whole (global) fixed to variable. This test is performed by comparing the value of Prob > chi2 the F-table. Based on the test results calculations, the F-statistics generated by Probis bigger than > chi2 (Table 12), while the obtained results is at 0.0000. Therefore, as a test of the overall variable Foreign Capital Investment (FCI), Domestic Capital Investment (DCI) in agriculture, agricultural laborers, exchange rate, and the BI Rate have simultaneously a significant effect on the variable Gross Domestic Regional Product (GDRP) of agriculture in West Java.

This test conducted to measure the variation of the value of the dependent variable can be explained by variations in the value of the independent variable. The

coefficient of result determination (R2) of the selection panel models has been determined. It is the coefficient of determination of the test Fixed Effect (FE) which was also within the amount of 0.9500. This shows that every additional independent variable, hence variation of the independent variables in the model is able to explain the variation in the dependent variable by 95%, while the remaining 5% is explained by other variables outside the model (Table 14).

Interpretation and analysis of the results of estimation are described as followed:

- (1) Foreign Capital Investment (FCI) has positive and significant effect on GDRP amounted to 0,1229657
- (2) Domestic Capital Investment (DCI) has positive and insignificant effect on GDRP amounted to 0.0434732.
- (3) Labor have positive and insignificant effect on GDRP amounted to 0.152439.
- (4) Exchange Rate has positive and significant influence on GDRP amounted to 4.413201.
- (5) BI rate has negative and significant effect GDRP amounted to 1.550976.

The study by Sodik and Nuryadin (2005) stated that Foreign and Domestic Investment gives affects to the regional economic growth. Izuchukwu (2011) finding reveals that there is a positive relationship between Gross Domestic Product (GDP) and three independent variables (Domestic Saving, Government Expenditure on Agriculture and Foreign Direct investment in Agriculture). The study of Faiziah and Sofyan (2014) indicated that the investment give effect on GDRP. Results from Maqin (2011) showed that the electric infrastructure, manpower and development expenditure have positive and significant impact to GDRP. The study of Utomo, et. al. (2015) showed that investment in the agricultural sector will be able to enlarge and expand its production capacity in East Java, including raising the economy impact on the formation of income/ salaries for workers. The study of Novita et. al. (2009) showed that the impact of agricultural investment is happening to the formation of the output, income, and the creation of employment. Meanwhile, the study of Lenggogeni (2012) showed that the exchange rate significantly gave influences to the agricultural sector investment.

There is a difference between this study and the previous ones. The difference is that domestic capital investment and manpower has no significant effect on GDRP. This can happen because GDRP of West Java is dominated by the manufacturing / processing. The low-increasing contribution of agriculture to GDRP in West Java occur based on the phenomenon of high-ranked poverty in Indonesia related to the agricultural sector (Suryahadi and Gracia, 2011). Domestic investors and manpower are not interested in investing or working in the agricultural sector, due to the perception of poverty

and risk.

Fixed effect model allows the analysis of the individual effect of each district/city to be interpreted as the position of the relative potency of a district/town area of the district/city. Intercept of each district/city means that if there is no influence of all independent variables, the GDRP in each district/city was respectively in accordance with the value of intercept (Table 15). There are nine districts/cities that have a positive intercept and remain negative.

Positive intercept indicates that districts/cities have higher GDRP than the other. Highest intercept value was in Indramayu (1.438182). It meant that the heterogeneity compared to other districts/cities can encourage higher GDRP. Positive intercepts indicate that the pointed areas highly contributed to farm. Lowest intercept value was in Cimahi (-3.931598). Negative intercept is an area of low agricultural contribution, generally those which are categorized as industrial services areas, such as Bandung, Cirebon, Bogor, Bekasi, Karawang. Therefore, these are areas of industrial/service which give negative contribution in agricultural sector to GDRP.

CONCLUSION

The study uses panel data from 26 regencies/cities in West Java from 2007-2012. The conclusions are:

1. Foreign Capital Investment (FCI) has a positive and significant effect in improving the agricultural sector GDRP in West Java.
2. Domestic Capital Investment (DCI) is positive but not significant effect in improving the agricultural sector GDRP in West Java
3. Labor have not significant positive effect but improving the agricultural sector GDRP.
4. Exchange rate have positive and significant effect in improving the agricultural sector GDRP in West Java.
5. BI Rate have negative and significant effect on GDRP.

In improving the agricultural sector in West Java. Advice to authors based on the results of this research to:

1. Central Government:
 - a. Foreign Capital Investment (FCI) is enhanced to boost regional economic growth by facilitating the investors to invest in the agricultural sector in particular.
 - b. Domestic Capital Investment (DCI) is supposed to compensate foreign investment, especially in agriculture by always doing RnD (Research and Development) in order to create improved clones or processed products. Therefore, domestic/local investors will be interested in investing to the agricultural sector.
2. Bank Indonesia:

- a. Setting a BI policy in accordance with the safe limit to investors interested in investing.
- b. Stabilization of the exchange rate for the purposes of agricultural inputs.
3. It is necessary to increased productivity and quality of labor, in order to increase investment opportunities in the agricultural sector.

Table 12. F-statistic Critical Boundary Value

N2 (k-1)	N1 (n-k)	F-table		
		$\alpha = 0,1$	$\alpha = 0,05$	$\alpha = 0,01$
5	20	3,21	4,56	9,55

N1 = df numerator (k-1; 6-1 = 5)

N2 = dfdenominator (n-k; 26-6 = 20)

Table 15. Intercept value in each district/city in West Java Province

No	District or city	Coefficient
1	Bandung District	0,0751325
2	Bekasi District	-0,710196
3	Bogor District	-0,1449752
4	Cianjur District	0,2742127
5	Cirebon District	0,5102275
6	Indramayu District	1,438182
7	Karawang District	-0,0865766
8	Purwakarta District	-0,7582612
9	Subang Distric	0,6002636
10	Sukabumi District	1,084711
11	Sumedang District	0,5399255
12	Bandung City	-2,632238
13	Banjar City	0,9159898
14	Bekasi City	-1,61832
15	Bogor City	-3,622806
16	Cimahi City	-3,931598
17	Cirebon City	-2,762146
18	Depok City	-1,839146
